# **Introduction**

## **SatNOGS Optical**

---

The SatNOGS Optical Unofficial Guide documents how to set up and run an optical ground station for the LSF's SatNOGS network.

## Unofficial Guide Overview

First, an overview of the this text, then the LSF and some of it's key projects, such as the SatNOGS network. A cursory review of satellites and existing RF ground stations will be followed by a big picture view of acquiring and processing images of satellites. Hardware is reviewed, then software to run on it, with many options, including what is best. Finally, what to do with the data (IDK!). The chapters that follow are listed below.

**Satellites** — What are we looking at?

**Ground Stations** — How Earth talks to satellites and back.

**Toolchain and Process** — The big picture of what hardware and software is needed to set up an optical ground station for use on the network.

**Hardware** — Details on appropriate hardware configurations, and example setups.

**Software** — A look at the myriad software related to satellites, and what works best at present for SatNOGS Optical.

**Acquire** — Convert photons to bits. Pointing a camera at the sky works.

**Solve** — Pictures of stars reveal the time and location of the photo. Plate solvers reviewed.

**Detect** — The plate solver says where the photo is, now detect if are there moving trails that aren't star trails that could be satellites.

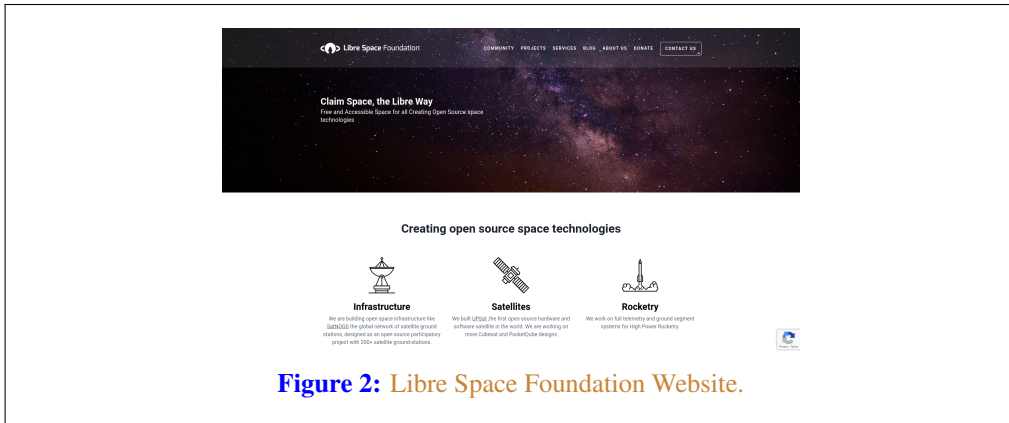

**Identify** — With time, location, satellite detection, TLEs are overlaid and compared with detected satellites. Satellite identification by computers and humans.

**Upload** — When ready, data will be pushed to the SatNOGS network.

**Support** — Where development is occurring and questions answered!

## Libre Space Foundation

The LSF supports “free and accessible space for all, creating Open Source space technologies.”<sup>1</sup>

Select LSF projects:

**SatNOGS** — Global network of satellite ground stations

<https://satnogs.org>

**UPSat** — First OSH and OSS satellite in the world

<https://upsat.gr/>

## SatNOGS Network

SatNOGS is the LSF’s global network of satellite ground stations.

## Optical Network Status

The SatNOGS RF network has been running successfully for years. Adding an optical network is a new development. At present there are zero nodes on the network.

<sup>1</sup><https://libre.space>

## Introduction

Some software already exists, some is being ported from C to Python, and other parts remain to be done. There is software available for acquiring optical data of satellites. There is no facility at present for pushing data back to the network.

---

# **Satellites**

## **Artificial Satellites in Space**

---

## 1.1 Overview of Satellites

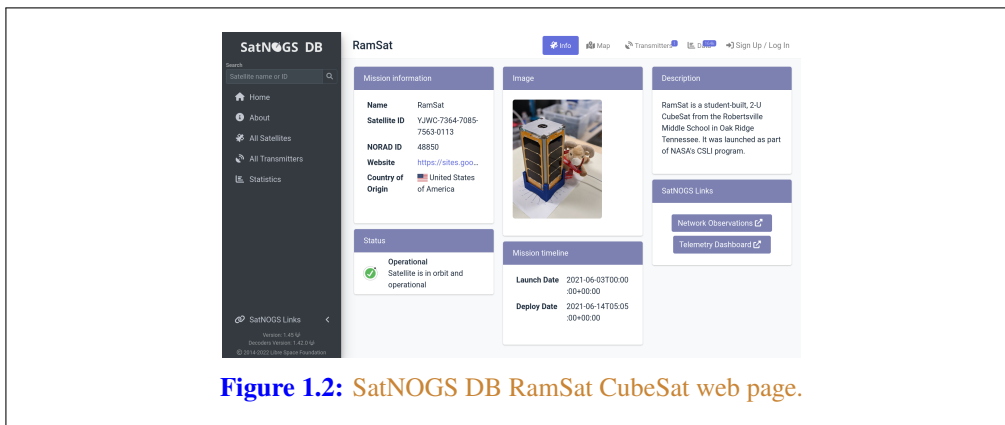

This chapter gives a brief overview of satellites, with particular attention to ones using amateur radio bands.

## 1.2 SatNOGS DB

The SatNOGS DB is a database that lists satellites, many of which can be tracked by ground station operators on the SatNOGS network.

Individual satellites can be viewed, such as the RamSat CubeSat.

## 1.3. LIBRE SATELLITES

For some satellites, telemetry is available in a Grafana dashboard. See the RamSat telemetry dashboard.

### 1.3 Libre Satellites

Below are satellites in orbit, decayed, or designs on Earth that generally support the libre way. These are some select libre satellites:

**UPSat** — First libre OSH and OSS satellite in the world. Created by the LSF.  
<https://upsat.gr/>

RF Observations can be scheduled on the SatNOGS network. See figure 1.5, page 19 for a example list of observations of the RamSat CubeSat.<sup>1</sup>

Individual RF observations are uploaded to the SatNOGS network, as can be seen in the example observation of the RamSat CubeSat by SatNOGS ground station “2380 - Piszkesteto UHF” run by volunteer bcsak (username).

### 1.4 Satellite Orbits

Satellite orbits. See SGP and SDP.

See TLE.

# **Ground Stations**

## **Looking up from Earth**

---

## 2.1 Overview of Ground Stations

Ground stations are a setup of equipment such as embedded systems, cameras, SDRs, antennas, and receivers, located on Earth, observing space.

## 2.2 SatNOGS Ground Stations

The LSF built the SatNOGS network using distributed, volunteer-run, RF ground stations using SDRs, such as in figure 2.1, page 23.<sup>1</sup> It shows a SatNOGS ground station with VHF (right) and UHF (left) antennas on a mast with an Alt/Az mount rotator. SDRs can be used as RF receivers.<sup>2</sup>

Ground stations can be viewed on the SatNOGS network website, such as as the example in figure 2.2, page 24.<sup>3</sup>

## 2.3 SatNOGS Optical Ground Stations

The LSF is developing SatNOGS Optical to add optical ground stations to the network.

Prototype optical ground stations are being developed. An example setup, using a Sky-Watcher EQ6-R Pro telescope tripod and tracking mount, can be seen in figure 2.3, page 25.

### 3.1 SatNOGS Optical HOWTO

SatNOGS Optical is the nascent distributed network of optical ground stations.

This chapter gives a top level review what is needed in terms of hardware and software to build an operating optical ground station.

### 3.2 Toolchain

See below for a SatNOGS Optical Process Overview.<sup>1</sup> See figure 3.1, page 29, described below.

**Hardware** — Hardware, such as cameras and embedded systems, is to be selected and set up.

**Software** — The best currently available software is to be downloaded, installed, and configured.

**Acquire** — Data samples, typically in the form of FITS file photographs, need to be acquired by running a camera outside at night taking pictures of the sky.

**Plate solver** — Acquired data samples in FITS files need to be processed by a plate solver. See section 7.1, page 66.

**Detect satellites** — Using TLEs and the “solved” plates, detect satellites. See section 8.1, page 70.

**Identify satellites** — With satellites detected in the previous step, identify what they are. See 9.1, page 74.

### 3.3 Hardware

Discussed in this section are some of the hardware options to be explored. More explicit instructions of a particular hardware installation can be see in section 4.1, page 34. Discussed below are camera options, for details on embedded systems and other parts, also see hardware in section 4.1, page 34

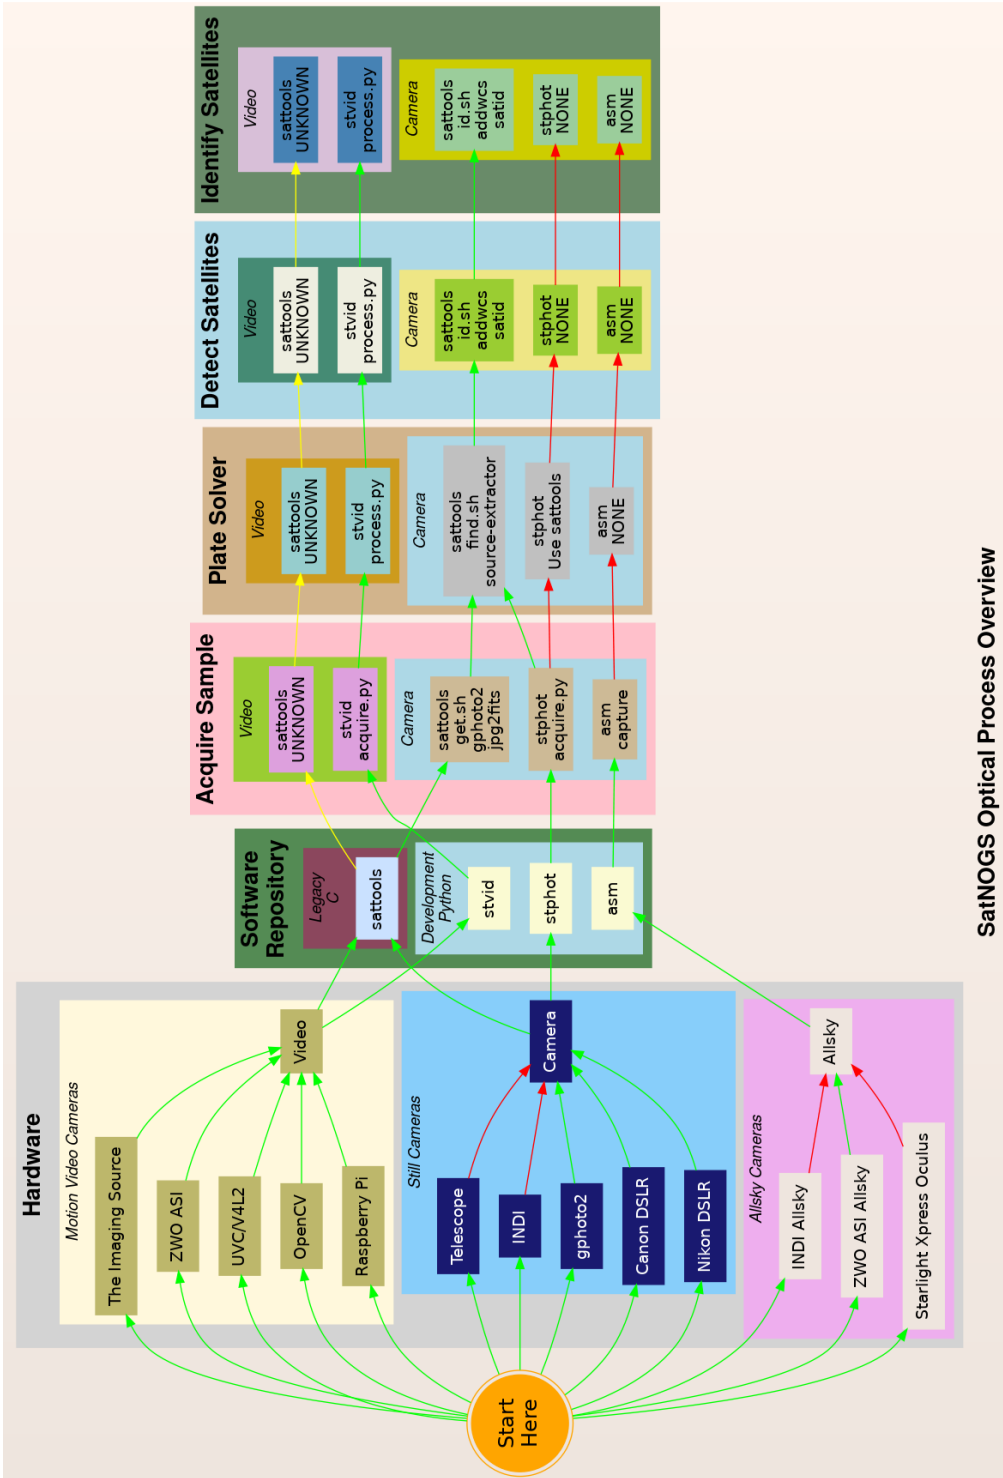

For the purposes here, there are three main categories of hardware. Depending which category of equipment is selected, it impacts everything else, such as the software used. Main categories:

**Motion video cameras** — Moving images.

**Still camera** — Still photos.

**Allsky cameras** — Views of all, or nearly all of the sky.

<sup>1</sup><https://spacecraft.org/spacecraft/SNOPO>

SatNOGS Optical Process Overview

Figure 3.1: SatNOGS Optical Process Overview

Different types of equipment can be used in different categories. Some can be used in multiple setups, most just in one. If available, using motion video cameras will work best for detecting satellites with the developing SatNOGS toolchain. Examples of motion video camera sources that could be used:

**The Imaging Source Cameras based on IMX174** — Known to work. Recommended. High quality cameras, believed to be usable following DFSG.

**ZWO ASI based on IMX174** — Known to work. Not DFSG compatible. Uses proprietary SDK. Currently in prototype development.

**UVC/V4L2** — “Any” video camera that works with the Linux kernel. Typically, the device will appear similar to `/dev/video0`. A camera that works with the software isn’t necessarily sensitive enough to detect satellites, however, as most are designed for brighter environments.

**OpenCV** — cameras that work with OpenCV can be used, same as UVC. To work well, they need to be sensitive.

**Raspberry Pi** — The PiCamera can be used. A good lower cost option. Recommended. Many non-Raspberry Pi devices, such as Odroid are also compatible with the Pi MIPI interface.

Still cameras can also be used productively. The current Python toolchain is in very early development and not completely usable yet.

See the list below for still camera options:

**Telescopes** — Can definitely take images of satellites. Not the best tool at present, as it isn’t well integrated into the SatNOGS Optical toolchain. The FOV is generally too small. The mounts are optimized for different types of tracking than satellites. This is changing, and longer term could be well-supported. Using RASA style astrographs is likely the best option.

**INDI** — Typically used for control of telescopes and associated instrumentation, such as tracking mounts and cameras. Cannot be used directly with the current developing SatNOGS toolchain. It is not seen as the future path forward as it isn’t well optimized for SatNOGS Optical usage. That said, it is very useful at present for running a tracking mount with KStars and Ekos, for example, in lieu of a better option. Camera software in the INDI platform typically produce image FITS files.

**gPhoto** — The Linux kernel recognizes many cameras that can be used with gPhoto tools and drivers, available in Debian. This is the recommended option at present for still cameras. DSLR cameras, such as from major manufacturers Canon and Nikon, are used with gPhoto.

Considering the hardware options above, they need to be matched with corresponding software. Not all options work (at all), and some cannot be easily used to perform all steps needed.

### 3.3. HARDWARE

There are also broader “paths” that need to be considered:

**sattools** — Deprecated because it is in C, and the decision by upstream and the LSF was made to move forward with applications primarily written in Python. Sattools is the most complete toolkit, however, so no matter what path is chosen, some parts of it will likely be used for now. It can be used with motion video cameras and still cameras. It includes many other software tools related to satellites.

**stvid** — This is the best path if a motion video camera is available. It is in Python and is the tool the SatNOGS Optical project is using as the basis for future development. It still depends on some C tools from sattools.

**stphot** — Written in Python this is what the SatNOGS Optical project will likely use in the future for still cameras. It is in very early development, but can acquire data (take photos) with gPhoto-compatible cameras.

**asm** — All Sky Monitor for taking pictures of all, or nearly all of the sky, such as with a 150 or 180 degree view. The asm application is in pre-development, but is in Python and could be the basis for future SatNOGS Optical development. The difficulty with all sky cameras is the plate solver isn’t written to use images from the “fish-eye” view of an all sky camera.

**Other** — There are many other satellite and telescope software packages freely available on the Internet. Perhaps some could be adapted for usage.

---

# **Hardware**

## **Design and Set Up Equipment**

---

## 4.1 Overview of Hardware

Hardware considerations for a SatNOGS Optical ground station.

Main hardware components in an optical ground station:

- Lens.
- Camera.
- Embedded system (computer).

Other components:

- Ethernet cable.
- USB cable.
- Enclosure.
- Power supply.
- Tripod.
- Manual or tracking mount.
- Power source, grid or alternative.
- Internet, wifi or ethernet.

## 4.2 Camera

Cameras being evaluated:

- The Imaging Source IMX174 based, monochrome.
- ZWO ASI174MM, monochrome.
- ZWO ASI1600MM Pro, monochrome.
- DSLR camera.
- PiCamera.

**NOTICE:**

ZWO/ASI cameras require proprietary non-libre software on host computer and is not DFSG compatible.

### 4.3 Lenses

For lenses, the faster the better. F1.2 works well. F1.8 is the maximum recommended.  
Lenses being tested:

- Kowa 50mm f1.4 C-mount.
- Canon EF 50mm f1.2 USM.

### 4.4 Embedded System

Embedded systems, such as Raspberry Pi, that can be used.

**Odroid N2** — Confirmed working.

**Odroid M1** — Testing.

**Raspberry Pi 3** — ?

**Raspberry Pi 4** — ?

**Intel NUC** — ?

#### 4.4.1 Embedded Systems Comparison

Comparing embedded systems for SatNOGS Optical.

| Make   | Model | Architecture | Max RAM | eMMC |  |
|--------|-------|--------------|---------|------|--|
| Odroid | N2    | ARM64        | 4 GB    | Yes  |  |
| Odroid | M1    | ARM64        | 8 GB    | Yes  |  |

**Table 4.1:** Comparison of embedded systems

### 4.5 Example Optical Ground Station with Tracking

This is an example of a tracking ground station. It is a prototype, so there are lots of mis-matched, overbuilt/underbuilt parts. The full setup on tripod, can be seen in 2.3, page 25.

A close up of the setup can be seen at 4.1, page 36, showing the Sky-Watcher telescope tracking mount, a Bosch PoE camera enclosure, and through the glass the camera lens. In the background is a white antenna for GNSS (GPS) and a solar power setup.

The camera lens is protected by the enclosure glass, which is IP67 (XXX) rated. See a close up of the front of the enclosure and camera lens in figure 4.2, page 37.

**Figure 4.1:** SatNOGS-Optical ground station prototype.

#### 4.5. EXAMPLE OPTICAL GROUND STATION WITH TRACKING

**Figure 4.2:** Camera enclosure, front side, showing glass and lens.

**Figure 4.3:** Camera enclosure, left side, showing hinge.

As seen in figure 4.3, page 37, the left side of the enclosure has a hinge for opening. The bottom white component is part of the telescope mount.

Figure 4.4, page 38, shows the right side of the enclosure. Two mounting bolt access points can be seen on each end. These are unscrewed with a hex head tool (supplied) to open the enclosure.

**Figure 4.4:** Camera enclosure, right side.

The enclosure is opened from the right side, as shown in figure 4.4, page 38. Inside the camera enclosure, as shown in Figure 4.6, page 41, is:

- The Imaging Source DMX camera with Sony IMX174 CMOS.
- Kowa 50mm f1.4 C-mount lens.
- Odroid N2 running Debian GNU Linux system.
- Odroid N2 plastic enclosure, large half, hole drilled for ad-hoc mounting.
- Blower fan on top, with power cable (came with Bosch enclosure).
- Fan, maybe not so useful, with power cable (came with Bosch enclosure).
- Camera mounting plate (came with Bosch enclosure).
- Camera mounting screws, M6x25 (?).
- Ethernet cable, internal, short white (came with Bosch enclosure).
- PoE ethernet cable, external, plugged into PoE switch for data and power.
- USB 3 cable, internal, way too long, needs replacing, from Odroid to camera. XXX flat connector
- USB 3 cable, external, from Odroid to telescope mount. XXX large rectangle connector
- “Custom” 12Volt (V) DC power cable from Bosch PoE to Odroid.

**Figure 4.5:** Camera enclosure, right side, opened.

- Assorted nuts, bolts, and washers for an ad-hoc standoff height.

The top of the enclosure shows weather protection and a sun visor. See figure 4.7, page 42.

## 4.6 Tripods

The camera setup can be mounted a wide variety of ways, from just setting the camera somewhere (worst option), to a heavy duty pier with tracking mount (best option).

At present, most prototype optical ground stations are using static mounts on tripods.

Tripod and similar options include:

**No mount** — Quick and dirty, just hang the camera out somewhere sitting on something.

**Small tripod** — There are small desk tripods than can be used with lighter setups, such as used with a Raspberry Pi PiCamera.

**Photography Tripod** — Using a common camera tripod, of which there is a wide variety, from light to heavy.

**Telescope Tripod** — Similar to photography tripods, but typically heavier weight.

**Telescope Portable Pier** — Similar to a telescope tripod, but much heavier, typically with a larger center pier post. Still movable, and folds up similar to a photography tripod.

**Telescope Pier** — A wide variety, such as making a roughly 1.5 meter permanent cement post.

## 4.7 Mounts

For mounts, there are two main types: tracking or static. By the latter “static” mounts, it is meant that the camera, the tripod, and the mount all stay motionless. This is what you would get using a camera with a common photography tripod and a simple mounting plate.

Static mounting options include:

**Camera plate** — Commonly used on cameras and readily available for mounting cameras to tripods.

**Enclosure plate** — A flat plate with holes drilled in it to mount the camera inside an enclosure.

**“Security” camera enclosure mount** — Various mounts exist to mount security cameras to posts, walls, etc.

Tracking mount options to consider include:

**Figure 4.6:** Camera enclosure, opened.

**Figure 4.7:** Camera enclosure, top.

**Sky-Watcher EQ6-R Pro** — Telescope mount using INDI.

**Celestron** — Wide variety of telescope mounts using INDI.

**iOptron** — Telescope mount with (untested) satellite tracking.

**INDI Telescope Mounts** — A wide variety of other INDI compatible telescope mounts.

**Yaesu G-5500** — Antenna rotator.

**hamlib** — Other hamlib compatible rotators.

**Teledyne FLIR PTU-5** — High Performance PTZ Unit designed for security cameras (untested, no drivers?).

**Misc PTZ** — Other security camera PTZ mounts.

Tracking mounts aren't widely used, but there is support for them in `stvid` when acquiring data. The tracking needs to be set up independently of `stvid`. At present, I use KStars with Ekos to control a Sky-Watcher EQ6-R Pro tracking mount.

For tracking, there are a few different ways to track:

**Static** — No tracking, just point at one place in the sky. Generates star trails. Generates satellite trails.

**Sidereal tracking** — Tracks stars. Generates stars as points. Generates satellite trails.

**Satellite tracking** — Tracks satellites. Generates star trails. Generates satellites as points or potentially larger images of the satellite structure.

### 4.7.1 Sidereal Tracking Mounts

Sidereal tracking (“telescope tracking”) is what COTS tracking “GoTo” telescopes from Celestron or Sky-Watcher do, for example. They track the stars, countering the rotation of the Earth to keep the same view of the sky in the camera’s FOV. Stars remain as points, even after multi-minute or multi-hour imaging. This is what is used for “pretty” pictures of stars, nebula, galaxies, etc. This is the most common tracking set up, as it has been widely used in astronomy communities for decades.

Within sidereal tracking mounts, there are yet more options:

**Fork** — Fork mount.

**EQ fork** — Fork on EQ mount.

**German EQ** — Most common EQ mount.

**More** — Endless variety of available telescope mounts.

Also related to sidereal tracking is lunar and planetary tracking, but for our uses all three will be included under sidereal tracking.

To use a sidereal tracking mount for imaging satellites, the camera must “leap frog” the satellite. At present, my practice is to use a sidereal mount, point at a location with KStars, start stvid. Then stop stvid, move to new location using KStars, start stvid.

See Software section 5.5, 50 for information on using tracking mounts.

### 4.7.2 Satellite Tracking Mounts

Of the options between a static mount (no tracking), sidereal tracking, and satellite tracking, the latter is by far the least common. In this case, the tracking mount is tracking the satellite itself. This is much more complex than tracking stars, which it builds upon. It requires, such as:

**Time** — Accurate time, such as from GNSS.

**Location** — Accurate location, also available from GNSS.

**TLE** — Need to know the satellites’ orbit (accurately!).

**Variable speed tracking** — Satellites are moving at different speeds above, the mount needs to be capable of that.

**Alignment** — On top of all the gear and software needed, the equipment needs to be accurately aligned.

Most tracking equipment for telescopes, cameras, and antennas usually has just a few speeds, such as a slew speed and a sidereal star tracking speed. Sometimes there will be a few steps of these speeds (e.g. slew speeds from 1-9), but not the finely tuned tracking speeds needed to track a satellite. Oftentimes the telescope tracking maximum speed will be too slow for satellite tracking.

Variable speed tracking (XXX phrase?) is needed for tracking satellites if the goal is to keep the satellite in the (near) center of the image frame and leave star trails. The speed the mount moves needs to be calculated based upon a recent orbit calculation, such as from a TLE.

There are highly skilled amateur astronomers that have captured detailed pictures of artificial satellites, such as the ISS and astronauts doing space walks, using hand guided telescopes with low cost CCD imagers.

There are few options for satellite tracking mounts. Some new iOptron telescope mount firmware supports tracking satellites. This has been largely untested so far, but at present is likely the best option, if a satellite tracking mount is wanted.

## **4.8 Future Designs**

There is some discussion of using much larger “lenses”, such as a RASA “telescope” (See: astrograph). The primary concern is the lack of satellite tracking mounts, because telescope mounts are generally too slow, and need to “leap frog” the satellite. Rotators used for antennas aren’t typically stable enough for a camera.

---

**Software**  
**Satellite Applications on Earth**

---

## 5.1 Software Overview

See 5.1, page 46 for a diagram with an overview of the software process.

**Figure 5.1:** SatNOGS Optical Operation Pipeline

## 5.2 Setup Optical Ground Station Software

HOWTO set up and configure a SatNOGS Optical ground station prototype. Note: the SatNOGS network is not yet ready for optical data.

For a description of installation using Docker, see section 5.9, page 56. For a “manual” install, see immediately below.

Setup an embedded system, such as a Raspberry Pi or an Odroid N2, with Debian stable (11/Bullseye) or testing (Bookworm).

See each software repository for latest documentation.

Install dependencies from the Debian software repository:

```

sudo apt update
sudo apt install python3-virtualenv python3-pip python3-dev \
source-extractor astrometry.net \
libeigen3-dev giza-dev libx11-dev \
astrometry-data-tycho2 astrometry-data-tycho2-07 \
astrometry-data-tycho2-08 astrometry-data-tycho2-09 \
astrometry-data-tycho2-10-19
  
```

Next, install the hough3d-code dependency.

```

git clone https://gitlab.com/pierros/hough3d-code
cd hough3d-code
make all
sudo cp -p hough3dlines /usr/local/bin/hough3dlines
  
```

Install satpredict from using either the cbassa or spacecraft software repository.

```

cd ../
git clone https://spacecraft.org/spacecraft/satpredict
# Or
#git clone https://github.com/cbassa/satpredict
cd satpredict/
make
sudo make install
  
```

### 5.3. CONFIGURE SOFTWARE

Now install `stvid`, the main acquisition and processing application. It is written in Python. Either use the spacecruft `git` software repository or the cbassa one.

```
cd ../
git clone https://spacecruft.org/spacecruft/stvid
# Or use upstream:
#git clone https://github.com/cbassa/stvid
```

Optionally, set up a Python virtual environment and use PIP:

```
cd stvid
virtualenv -p python3 env
source env/bin/activate
pip install --upgrade pip
```

Install dependencies. Numpy needs to be installed first, or the install fails.

```
pip install --upgrade numpy
pip install --upgrade -r requirements.txt
```

If the system `python3-numpy` conflicts, you could try installing `numpy` with PIP in the `virtualenv` thusly:

```
pip install --upgrade --ignore-installed numpy
```

Debian in bug #941466 changed the name of the `sextractor` dependency to `source-extractor`, so a symlink is needed for now:

```
sudo ln -s /usr/bin/source-extractor /usr/local/bin/sextractor
```

## 5.3 Configure Software

Configure the embedded system.

```
cd stvid/
cp -p configuration.ini-dist configuration.ini
# Edit
# Note for fields st-username and st-password, *don't* use quotes.
# Set:
vi configuration.ini
```

Edit various `configuration.ini` fields:

```
# For example:
observer_cospar = 9999          # COSPAR number of observer's site
observer_name = Jeff Moe       # Name of observer
observer_lat = 40.568912       # Latitude of location in decimal degrees
observer_lon = -105.225852     # Longitude of location in decimal degrees
observer_height = 1860         # Elevation of location in meters

observations_path = ./data/obs # Path for raw acquisitions
tle_path = ./data/tle         # Path where TLEs are stored (and updated)
```

```

results_path = ./data/results # Path for results of processed obs

st-username = foo
st-password = bar

# Path to source-extractor
sex_config = /usr/share/source-extractor/default.sex

```

Store downloads here:

```
mkdir -p ./data/obs ./data/tle ./data/results
```

The ST\_DATADIR variable is still used, from sattools. Maybe set all these in `./bashrc` (suit to fit directory setup):

```

export ST_DATADIR=$HOME/sattools
export ST_TLEDIR=$HOME/TLE
export ST_OBSDIR=$HOME/satobs
export ST_LOGIN="identity=foo@no:pass"

```

Set `astrometry.net` to run in parallel, assuming you have enough RAM: (This doesn't appear to work? Breaks?).

```

sudo vim /etc/astrometry.cfg
# Uncomment:
inparallel

```

## 5.4 skymap

Use `skymap` for viewing satellite orbits trails projected on a map of of the sky. `Skymap` is part of `sattools`. `Skymap` isn't a required part of the toolchain, but it is useful to see what satellites are visible at a particular time and location.

Source:

\* <https://github.com/cbassa/sattools>

My fork:

\* <https://spacecraft.org/spacecraft/sattools>

### NOTICE:

The main upstream `sattools` package requires non-libre `pgplot` on the host computer which is not DFSG compatible.

Described below is how to build and install my fork of `sattools` to use `skymap` instead of upstream. Upstream requires non-libre software which also happens to be very difficult for most users to compile. My fork uses the `Giza` library which replaces `pgplot`. It is much easier to build.

```

# Install dependencies
sudo apt install giza-dev git make dos2unix source-extractor wcslib-dev \
    libgs1-dev gfortran libpng-dev libx11-dev libjpeg-dev libexif-dev

# Clone repo
git clone https://spacecraft.org/spacecraft/sattools
# Or use upstream (needs more steps)

```

```

git clone https://github.com/cbassa/sattools

cd sattools/
# Build
make

# Install
sudo make install

# Clean
make clean

# To rebuild
make clean
make

# To uninstall
sudo make uninstall

```

See below for skymap (fork) usage:

```

tleupdate

# set config in ~/.bashrc XXX

skymap --help
Usage: skymap [OPTION]
Visualize satellites on a map of the sky.

-t, --time      Date/time (yyyy-mm-ddThh:mm:ss.sss) [default: now]
-c, --catalog  TLE catalog file [default: satnogs.tle]
-i, --id       Satellite ID (NORAD) [default: all]
-R, --ra       R.A. [hh:mm:ss.sss]
-D, --decl     Decl. [+dd:mm:ss.ss]
-A, --azimuth  Azimuth (deg)
-E, --elevation Elevation (deg)
-w, --width    Screen width (default: 1024). Set height too.
-g, --height   Screen height (default: 768). Set width too.
-n, --mmax     nmax line resolution/speed (default 128)
-S, --all-night All night
-Q, --no-stars No stars
-a, --all-objects Show all objects from catalog (default: LEO)
-h, --help     This help
-s, --site     Site (COSPAR)
-d, --iod      IOD observations
-l, --length   Trail length [default: 60s]
-P, --planar-id planar search satellite ID
-r, --planar-alt planar search altitude
-V, --visibility-alt altitude for visibility contours
-p, --positions-file File with xyz positions
-L, --longitude manual site longitude (deg)
-B, --latitude manual site latitude (deg)
-H, --elevation manual site elevation (m)

```

## 5.5 Tracking Software

The tracking software used depends upon the tracking mount.

See section 4.5, page 35 for discussion of hardware tracking mounts.

For our uses here, there are three broad categories of tracking software:

**Telescopes** — Controlling telescopes remotely.

**Antennas** — Controlling antennas remotely with hamlib.

**Cameras** — Controlling PTZ cameras remotely.

### 5.5.1 Telescope Tracking Software

Software that can be used with telescope tracking mounts:

**INDI** — Main client/server used by other applications.

**KStars** — Sky charts, INDI control.

**Ekos** — Application used within KStars for remote control of telescopes and related hardware via INDI.

**Stellarium** — Sky charts, has INDI plugin.

**Other INDI** — Many more applications work with INDI.

**INDIGO** — Positions itself as a next-generation INDI (?).

Using INDI with KStars and Ekos on a Sky-Watcher or Celestron telescope mount is a known working solution.

### 5.5.2 Antenna Tracking Software

At present, for the SatNOGS network RF ground stations, hamlib is typically used for tracking, if directional antennas are used. Hamlib was originally created for amateur radio equipment, but has expanded to control many more devices.

**hamlib** — Antenna rotator control.

I don't know of anyone prototyping a satellite tracking mount with hamlib, but it should be possible using the "leap frog" method, perhaps on the same mount as existing SatNOGS antennas. The mount may not be steady enough.

### 5.5.3 Camera Tracking Software

There are applications for using PTZ control of cameras, such as used in "security" cameras.

**motion** — PTZ camera control. XXX check

I don't know of any of these being used in satellite tracking prototypes at present.

## 5.6 GNSS with `gpsd`

GNSS is used for time synchronization and for (somewhat) accurately determining the location of the observation.

GNSS collectively includes the USA GPS, Europe's Galileo, Russia's GLONASS, and China's BDS, as well as other regional systems.

A basic, widely available COTS USB GNSS device with a basic (or no!) antenna plugged into the embedded system can get time and location accurate enough for the purposes here. See various U-Blox devices, for example.

In Debian GNSS service with a USB device can be provided by the `gpsd` application.

```
sudo apt install gpsd gpsd-tools
```

Edit the configuration file, `/etc/default/gpsd` like:

```
DEVICES="/dev/ttyACM0"
GPSD_OPTIONS="-Gn"
USBAUTO="false"
```

This will start a `gpsd` daemon listening on all interfaces, so it can be used by other computers on the network (such as if acquire and process are on different machines). Using the device `/dev/ttyACM0` can be problematic if there are multiple `/dev/ttyACM*` devices. Perhaps something like this could be used in that case:

```
DEVICES="/dev/serial/by-id/usb-u-blox_AG_-_www.u-blox.com_u-blox_GNSS_receiver-if00"
```

Even with `gpsd` configuration listening on all IPs, don't think `systemd` won't do what it likes. So you may have to do:

```
systemctl edit --full gpsd.socket
```

And create a `gpsd` configuration like this (I have IPv6 disabled, in this case):

```
[Unit]
Description=GPS (Global Positioning System) Daemon Sockets

[Socket]
ListenStream=/run/gpsd.sock
# ListenStream=[::]:2947
ListenStream=0.0.0.0:2947
SocketMode=0600
BindIPv6Only=no

[Install]
WantedBy=sockets.target
```

(Re)start:

## 5.7. NTP

```
sudo systemctl restart gpsd.service gpsd.socket
```

Test all is good:

```
gpsmon -n  
# or  
cgps -u m
```

Enable to start on boot:

```
sudo systemctl enable gpsd.service gpsd.socket
```

See below for sample output from cgps.

```

```

## 5.7 NTP

With all the above, time still needs to be configured. Configuring `gpsd` isn't enough for correct system time. The main system on the Internet used for time synchronization is NTP. In Debian there are a few options for NTP. The best is to use a hardware GNSS (GPS), with PPS for improved accuracy. The easiest is to just use NTP.

All systems in the pipeline need to have the correct time and location. It is best if they all pull from the same NTP server, or even better than best if they all run GNSS hardware with PPS enabled.

Some quick and dirty time synchronization commands. The `ntpd` daemon can have slow startup synchronization sometimes. If so, perhaps run like this:

```

# Get the daemon out of the way.
sudo systemctl stop ntp

# Get time from someone, MIT in this case:
sudo ntpdate time.mit.edu

# OR

# Get time from local server, such as router (made up IP):
sudo ntpdate 192.168.1.1

# Restart daemon
sudo systemctl start ntp

```

Go through each of the systems used in the toolchain and make sure they all have accurate time or processing will be off.

## 5.8 KStars with Tracking Mount

KStars is an application that has been used for years in the astronomy community. It is well established, well supported and included in Debian.

KStars has multiple uses for imaging satellites. One main use is to control a telescope tracking mount, such as the hardware described in section 4.7, page 40.

For the purposes here, described below will be using KStars with a Sky-Watcher tracking mount with INDI and Ekos. See figure 2.3, page 25 for a photo of the setup used with KStars below.

The telescope mount will be used in sidereal tracking mode, where the stars will appear as “points”, and the satellites will appear as trails. The mount is not used in a satellite tracking mode. Sidereal is the “standard” tracking mode of telescopes.

KStars is the “main” application, but it depends on other key parts. INDI is the protocol that KStars uses for telescope control. INDI itself is a collection of applications. While KStars has the main sky chart and Ekos is launched within it, the actual mount control is done with the Ekos application. While it may sound complex, all of this is set up pretty easily in Debian.

```

# Quick and dirty from memory, something like:
sudo apt update
sudo apt install kstars indi-bin indi-eqmod indi-gpsd

```

KStars has a sky chart, as can be see in figure 5.3, page 57. When mount control is functioning, a location on the sky chart, such as a star, can be clicked on and the mount will GoTo that location and optionally track it. Using this, a telescope mount can be used to easily point the camera at a location and track it to observe telescopes. It should also provide a superior FITS file for extracting data than using a static mount (XXX made up).

To use a telescope tracking mount for use with `stvid`, the following steps need to be performed in roughly this order, assuming everything has been configured. An overview of steps:

1. Physically mount all hardware.
2. Plug in and power everything up.

## 5.8. KSTARS WITH TRACKING MOUNT

3. Confirm all hardware looks ok (e.g. `lsusb`).
4. Confirm GNSS time and location are ok (e.g. `cgps -u m`). See section 5.6, page 52.
5. Confirm time is correct on all systems in the toolchain (e.g. `date`). See section 5.7, page 53.
6. Run camera configuration script (e.g. `v4l2-ctl` commands).
7. Start `indiserver` on the embedded system, using scripts to include a camera (such as `indi_v4l2_ccd`).
8. Start KStars on the workstation.
9. Launch Ekos within KStars, under **Tools**.
10. In Ekos, select a configuration with the EQ Mount for the Sky-Watcher, and V4L2 for the CCD, which will work with The Imaging Source camera used in this example. Alternatively, the ZWO ASI could be used with a similar configuration.
11. The Ekos configuration should also be set to use the remote `indiserver` IP address of the embedded system USB connected to the Sky-Watcher mount.
12. Hit the start button to start Ekos/INDI.
13. On the screen that pops up, confirm all the tabs are good.
14. Check the last configuration tab for the camera, it often resets the size.
15. Hit close on the screen with the INDI devices.
16. Click the mount icon, and start tracking.
17. Perhaps do some focusing... XXX
18. Click the solver icon.
19. Click the Sync radio button.
20. Click Capture and Solve. XXX what is it.
21. If everything is tracking happily, good.
22. If not, do all the alignment steps.
23. When alignment is good and tracking is accurate, stop Ekos and close it.
24. Stop the `indiserver` running on the embedded system.
25. Start the `indiserver` on the embedded system, but without using a camera (e.g. remove `indi_v4l2_ccd`).

26. Select the INDI configuration with a remote indiserver, the EQ Mount, and the Simulated CCD.
27. Hit start in Ekos to get INDI connections going.
28. Confirm all is ok in hardware tabs, then hit close.
29. Now in the KStars sky chart window there is control of the mount without interfering with the camera.
30. Start stvid. See XXX for more info.
31. When done capturing that part of the sky with stvid, stop stvid
32. Go to the KStars sky chart and right-click on the new location, and slew to it.
33. Start stvid again, pointing at the new location.
34. Repeat the last few steps each time a new sky location is desired.

If the camera and mount are connected to the embedded system OK, it will look like below, in this case with The Imaging Source camera and Sky-Watcher mount:

```
jebba@odroid-01:~$ lsusb
Bus 002 Device 003: ID 199e:9004 The Imaging Source Europe GmbH DMK 33UX174
Bus 002 Device 002: ID 05e3:0620 Genesys Logic, Inc. GL3523 Hub
Bus 002 Device 001: ID 1d6b:0003 Linux Foundation 3.0 root hub
Bus 001 Device 003: ID 067b:23d3 Prolific Technology, Inc. USB-Serial Controller
Bus 001 Device 002: ID 05e3:0610 Genesys Logic, Inc. Hub
Bus 001 Device 001: ID 1d6b:0002 Linux Foundation 2.0 root hub
```

Note the The Imaging Source Europe GmbH DMK 33UX174 device is the camera and the Prolific Technology, Inc. USB-Serial Controller is the Sky-Watcher telescope mount. Other views of the devices:

```
jebba@odroid-01:~$ ls -l /dev/bus/usb/002/003 /dev/bus/usb/001/003 /dev/video* /dev/ttyUSB0
crw-rw---- 1 root plugdev 189, 2 Sep 1 20:08 /dev/bus/usb/001/003
crw-rw-rw- 1 root video 189, 130 Sep 1 20:08 /dev/bus/usb/002/003
crw-rw---- 1 root dialout 188, 0 Sep 1 20:08 /dev/ttyUSB0
crw-rw---- 1 root video 81, 0 Sep 1 20:08 /dev/video0
crw-rw---- 1 root video 81, 1 Sep 1 20:08 /dev/video1
crw-rw---- 1 root video 81, 2 Sep 1 20:08 /dev/video2
```

Side note: you need to be in the plugdev, video, dialout groups. Side note: on the Odroid N2, there is another /dev/video device, so three devices are appearing. The The Imaging Source camera appears as two /dev/video devices.

## 5.9 stvid with Docker

Daniel Ekman has created a Docker setup for easier installation and configuration.

The Docker source code repo is available here:

\* <https://github.com/kng/stvid-docker>

The Docker itself is here:

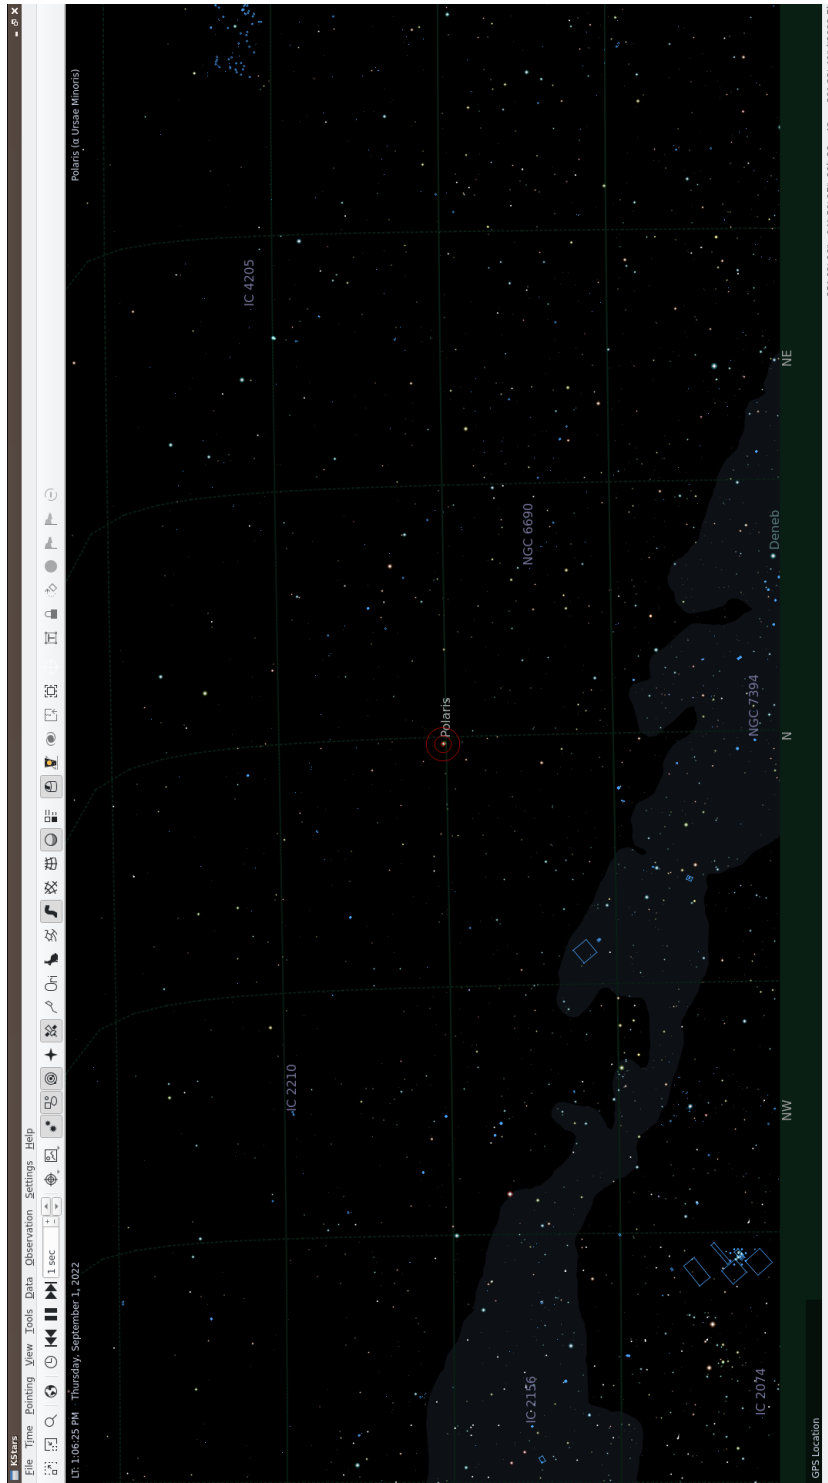

Figure 5.3: KStars sky chart, example screenshot.

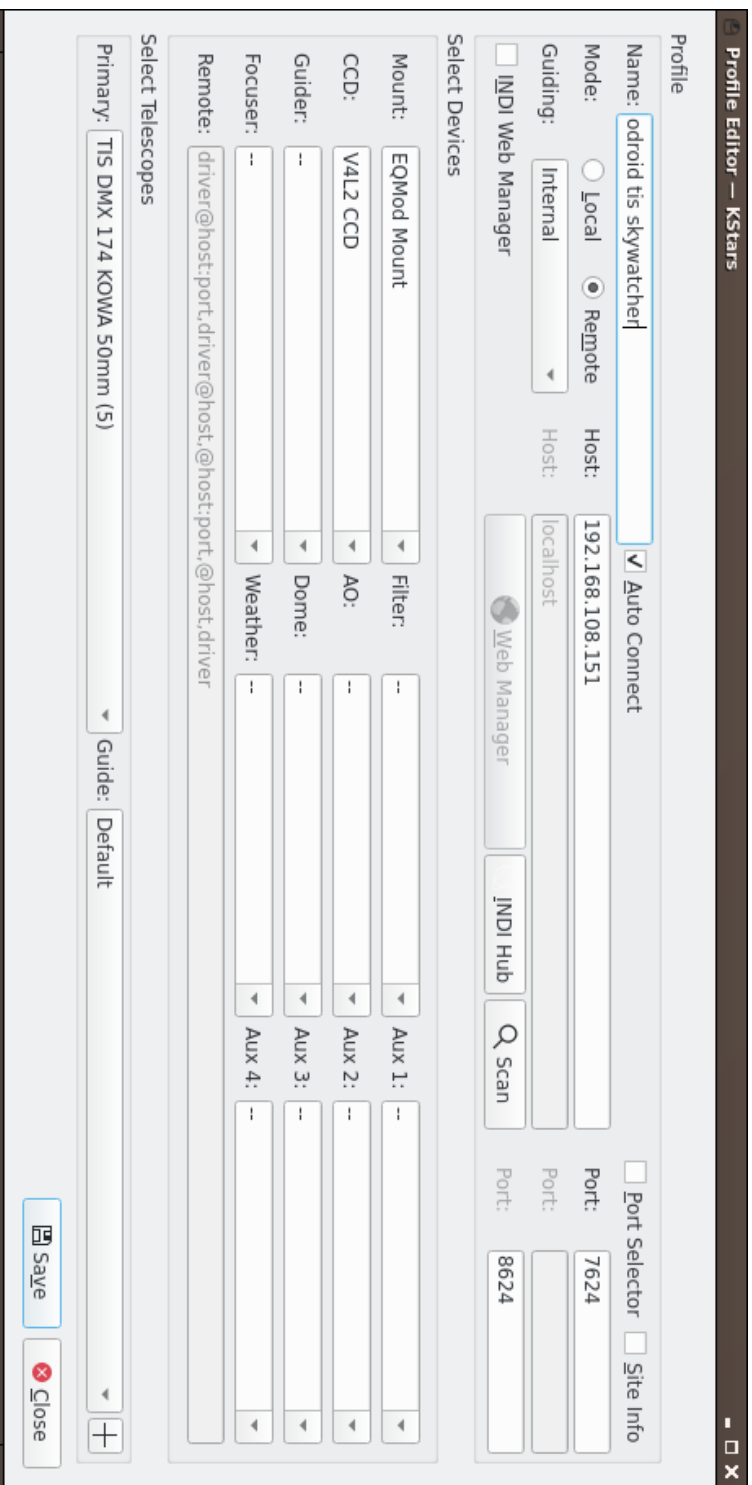

Figure 5.4: KStars using V4L2, example screenshot.

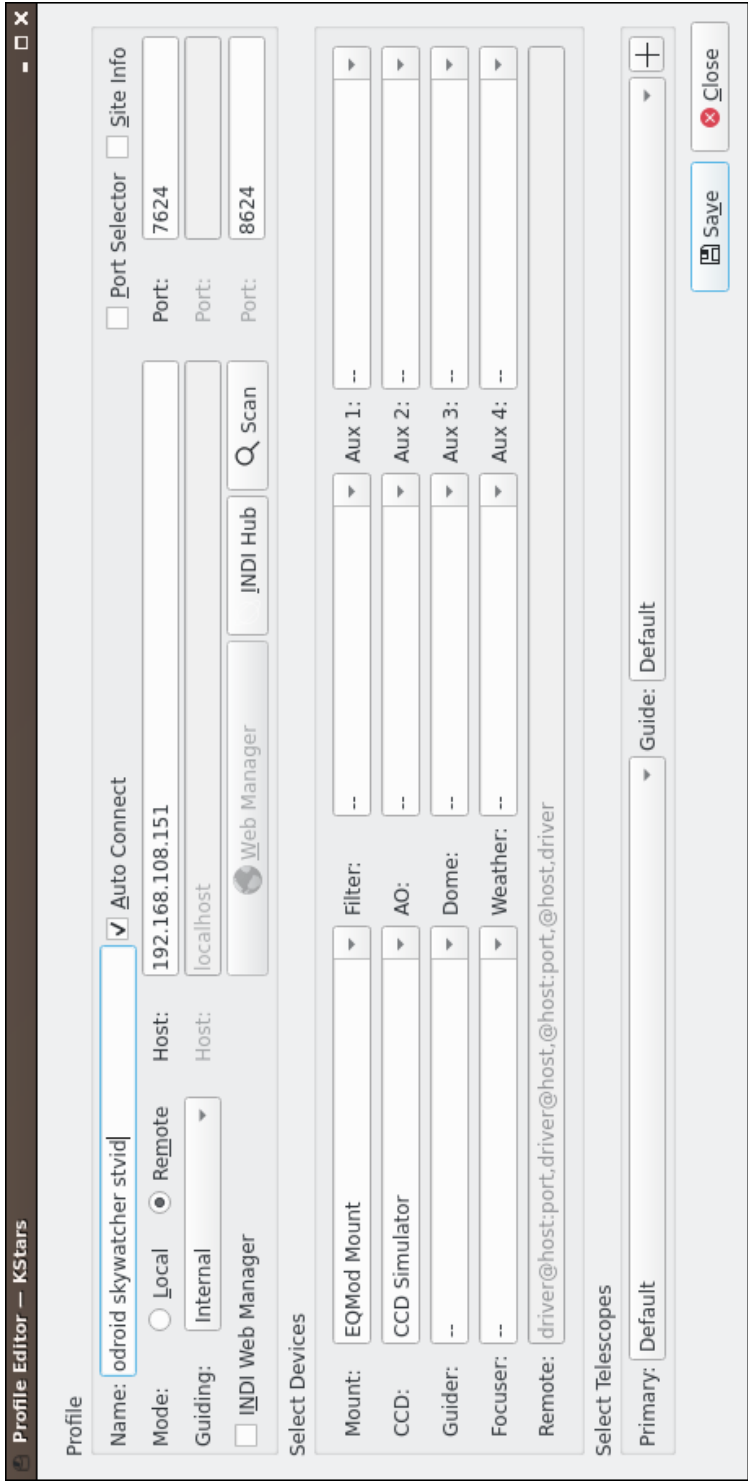

Figure 5.5: KStars using simulated CCD, example screenshot.

*Software*

\* <https://hub.docker.com/repository/docker/knegge/stvid>

---

**Acquire Data**  
**Twinkle, Twinkle, Little Starlink**

---

## 6.1 Overview of Operation

Below shows how to run a SatNOGS Optical ground station, after it has been set up and configured.

## 6.2 Setup with stvid

Acquire data with `acquire.py` from `stvid`. Enter `virtualenv`, if used:

```
cd stvid/
source env/bin/activate
```

Get the latest TLEs:

```
./update_tle.py
```

Acquire live data from camera.

```
cd stvid/
./acquire.py
```

## 6.3 `acquire.py` Output

Example output while running `acquire.py`.

```

**Figure 6.1:** Satellite images acquired by stvid.

---

**Plate Solvers**  
**Place from Pixels**

---

## 7.1 Plate Solver

A “plate solver” will take an image of stars and detect the time and place of the picture. There are two main steps:

1. Extract stars from an image, such as a FITS file generated by `stvid`.
2. “Solve” the image of the stars in the image against vast databases in a star catalogue.

See below for a list of software tools that detect/extract stars from images (e.g. FITS).

- Source Extractor.
- KStars with Ekos adds `Internal SEP`.
- KStars with Ekos adds `Builtin method for solver`.

See below for a list of plate solvers that can be used.

- `astrometry.net` locally.
- `astrometry.net` Internet.
- `astap`.
- `Watney`.

## 7.2 Source Extractor

Source Extractor, formerly SExtractor and some other names, is an application to extract stars from images. The software has been widely used for many years.

<https://www.astromatic.net/software/sextractor>

## 7.3 astrometry.net

Astrometry.net is a website and software that can be run locally to solve a plate of stars that has been extracted from Source Extractor. XXX

**NOTICE:**

Using `astrometry.net` online requires an account with non-libre services. The `astrometry.net` software can be installed locally to avoid this.

## 7.4 Star Catalogues

To use a plate solver, you will need star catalogues. They can get large. The `stvid` application includes a basic star catalogue. XXX The 4200 index series is also recommended.

## 7.5. WORLD COORDINATE SYSTEM

### 7.5 World Coordinate System

WCS info. XXX

### 7.6 SIP

SIP info. XXX

### 7.7 Plate Solving with stvid

Use the process.py scripts described in section 7.1, page 66, to solve plates with stvid.

---

**Detect**  
**Find Satellites**

---

## 8.1 Satellite Detection with stvid

This is a description of satellite detection processes. To detect satellite in a FITS file using the stvid toolchain, run `process.py` or, if it exists, the `process_new.py` Python script.

Note the stvid application's `process.py` and `process_new.py` will perform both the detection and identification steps.

### 8.1.1 process\_new.py Usage

This assumes you have installed stvid as shown in section 6.2, page 62. Adjust the dated directory used in this example to the actual directory name.

```
cd stvid/
# Maybe you need to update TLE
./update_tle.py
# Process directory
./process_new.py -c config_new.ini -d data/obs/20220825_1/020502/
```

### 8.1.2 process.py Usage

If there is no `process_new.py` it has likely been merged into `process.py`. Or perhaps, to use the “older” script it would be run as shown below. Note, the old and new configuration files are different and should be used with the correct corresponding Python script.

```
cd stvid/
./process.py -c configuration.ini -d data/obs/20220825_1/020502/
```

### 8.1.3 process\_new.py Example Output

```
Computing astrometric calibration for

## 9.1 Overview of Satellite Identification

The LSF is developing a project called SIDLOC, for satellite identification and localization. With the addition of many more satellites in orbit there is a growing need for SSA.

## 9.2 `stvid`'s `process.py` for Identification

The best tool for identifying satellites from FITS files is the `process.py` script from `stvid`, available here:

\* <https://github.com/cbassa/stvid>

My fork is here:

\* <https://spacecraft.org/spacecraft/stvid>

## 9.3 Identifying Satellites with `satid`

The deprecated C application, `satid` from the `sattools` package can help identify satellites. See figure 9.1, page 75 for output from my Giza port of `satid`.<sup>1</sup>

\* <https://github.com/cbassa/sattools>

My fork is here:

\* <https://spacecraft.org/spacecraft/sattools>

## 9.4 Identification with `stvid`

See section 8.1, page 70 for details on identification with `stvid`. The detection and identification steps are both done in one script.

See figure 9.2, page 76 for an example of from `stvid` automated processing of an input FITS file. The output image is in PNG format. `stvid` will also output other files with results, such as CSV files.

## 9.5 Review of Images

See the following subsections for example output from `stvid`.

### 9.5.1 Unidentified Satellites

When `stvid` runs the `process.py` (or `new`) script and it encounters a satellite it cannot identify, it gives it the NORAD ID 90000. If more unidentified satellites are detected in the same image, each detection is incremented by one.

See figure 9.3, page 77, for an example image, with three unidentified satellites. One is on the left, the other two on the right, next to each other.

See figures 9.4, 9.5, and 9.6, pages 78, 79, and 80, to see an example of `stvid` labelling three identified satellites with NORAD IDs 90000, 90001, 90002.

**Figure 9.6:** stvid processed image, with three unidentified satellites, the third labeled with NORAD ID 90002.

### 9.5.2 Airplanes

Airplanes are noise in the data.

Airplanes will appear not infrequently in images. See figure 9.7, page 82 for an example with an airplane in the left side, forming two parallel lines from the aircrafts' lights.

In figure 9.8, page 83, is shown an example image with an airplane with a very distinct blinking light.

In figure 9.9, page 84, airplane solid parallel lights can be seen with blinking lights.

### 9.5.3 Configuration and Setup Errors in Images

See figure 9.10, page 85, for an example of an image processed by a mis-configured system. As can be seen, the plotted lines are offset from the actual images of satellites. This, and similar issues, can be addressed by checking:

- Recent TLEs on both the processing workstation and the embedded system.
- Correct, NTP (or better) synchronized time on on the processing workstation and the embedded system.
- Correct latitude, longitude, and altitude are set in configuration files, typically based on GNSS readings.

### 9.5.4 Image Processed with Bad TLE

In figure 9.11, page 86, can be seen a FITS file that has been processed by stvid, but with TLEs that are around two days old. As can be seen, the satellites don't quite line up where they should.

### 9.5.5 Image Acquired During Slew

See figured 9.12, page 87, for an example image that is bad due to slewing during acquisition.

**Upload & Share**

**Send Data to the SatNOGS Network**

---

## 10.1 Push Data Upstream

The SatNOGS network isn't ready for optical data yet. So there is nothing that can be uploaded. This is under development.

## 10.2 File Extensions

The following file extensions are in use:

```
.cal — Cal  
.cat — Cat  
.csv — CSV  
.dat — Data.  
.fits — FITS.  
.png — PNG.
```

## 10.3 Data Files

After the `stvid` acquisition and processing steps have been run, files such as below will be generated:

```
2022-08-23T04:16:26.633.fits  
2022-08-23T04:16:26.633.fits.cal  
2022-08-23T04:16:26.633.fits.cat  
2022-08-23T04:16:26.633.fits.png  
2022-08-23T04:16:26.633_48473_catalog.dat  
2022-08-23T04:16:26.633_48473_catalog.png  
2022-08-23T04:16:26.633_52718_catalog.dat  
2022-08-23T04:16:26.633_52718_catalog.png  
2022-08-23T04:16:26.633_90000_unid.dat  
2022-08-23T04:16:26.633_90000_unid.png  
2022-08-23T04:16:26.633_hough.csv  
2022-08-23T04:16:26.633_predict.csv  
2022-08-23T04:16:26.633_threshold.csv
```

### 10.3.1 .fits FITS Files

FITS files are the main files created during acquisition and are the main files used in processing. It has the data of the actual image taken with the camera. FITS files will be significantly larger than the other files, at around 8 to 35 megabytes each, depending on sample rate, frame size, and binning.

The `stvid` program creates its customized FITS format file, which is a stack up of multiple images. I'll leave explanation of the `stvid` FITS file structure to the program's author, Cees Bassa:

## 10.3. DATA FILES

With stvid, I typically store 10 seconds worth of video frames, 100 frames at 10 Hz frame rate or 250 frames at 25 Hz frame rate into a so-called “four frame”. Here, for each pixel of the initial 100 or 250 frames, the mean, standard deviation, maximum and argmax are stored, each as its own frame. Objects that move will stand out because they will have a high  $(\max - \text{mean}) / \text{standard deviation}$ , which allows me to detect trails. Once a trail is detected, the argmax frame tells me the frame number and hence the motion of the trail, and using the timestamps of the individual 100 or 250 frames, I can reconstruct the pixel position as a function of time during the 10 second exposure, using only 4 frames instead of the 100 or 250 individual video frames.

### 10.3.2 .cal CAL Files

Example .cal filename:

```
2022-08-23T04:16:26.633.fits.cal
```

Sample data from .cal file, just the top select lines of a 577 line file:

```
1172.876  11.776  7.1775  221.117561  45.185979  6.761
786.524   1.817  6.0213  222.623526  37.272049  5.590
838.954  21.772  8.0430  222.941344  38.403949  7.653
872.352  25.919  8.3855  222.909215  39.103246  7.884
692.542  37.123  8.2615  223.889916  35.455924  8.718
738.829  47.126  8.2037  223.973142  36.430116  7.777
691.964  52.656  7.7910  224.278547  35.490201  7.411
951.962  53.159  8.0072  223.315748  40.816697  7.844
1209.704 60.030  6.0799  222.327791  46.116208  5.811
893.057  66.086  7.1867  223.943996  39.648460  8.039
...
```

### 10.3.3 .cat CAT Files

stvid generates .cat files, generated from FITS files, such as:

```
2022-08-23T04:16:26.633.fits.cat
```

Sample data from .cat file, just the top select lines of a 1,033 line file:

```
# 1 X_IMAGE           Object position along x           [pixel]
# 2 Y_IMAGE           Object position along y           [pixel]
# 3 MAG_BEST           Best of MAG_AUTO and MAG_ISOCOR  [mag]
# 4 FLUX_BEST          Best of FLUX_AUTO and FLUX_ISOCOR [count]
# 5 FLUX_MAX           Peak flux above background        [count]
# 6 BACKGROUND        Background at centroid position    [count]
1172.8755  11.7756  7.1775  33.80787  11.09625  16.06616
28.8250   11.4696  6.7443  50.38253  5.008112  15.81194

...

### 10.3.4 .fits.png FITS PNG Files

The `stvid` application can generate multiple PNG files, depending how many satellites it finds. In every case it creates at least one PNG file, with a name like:

2022-08-23T04:16:26.633.fits.png

In this image, as can be see in figure 10.1, page 92, no detected satellites are indicated. The blue lines are from the “Catalog”, which in this case means TLEs. The blue lines are drawn whether no, a few, or many satellites are detected. They are generated by taking data from the plate solver about where the picture FOV is, and overlaying satellite orbits that are calculated from TLEs.

The main blue line is slightly offset from where the satellite is calculated to appear. The blue line forms a small L shape. The smaller segment indicates the area where the satellite may pass. Next to the small segment line is the NORAD ID for the satellite. If it is unknown, it will be given the number 90000 or larger.

Figure 10.1: `stvid` PNG.

### 10.3.5 catalog.png catalog PNG Files

When `stvid` identifies a satellite, it creates a new PNG file for each satellite detected in the image. A file name example follows, with satellite NORAD ID 48473 identified, also shown in figure 10.2, page 93.

## 10.3. DATA FILES

2022-08-23T04:16:26.633\_48473\_catalog.png

**Figure 10.2:** stvid PNG of the satellite trail of NORAD ID 48473 identified in red.

If multiple satellites are detected in the image, they will each get a PNG file. For the example image, a satellite with NORAD ID 52718 was also identified. The file name is:

2022-08-23T04:16:26.633\_52718\_catalog.png

### 10.3.6 unid.png Unidentified PNG Files

As shown previously, stvid will create a new PNG with a red line when it identifies a satellite. When stvid finds a trail it can't identify in the TLE catalogs, it gives it a NORAD ID starting with 90000, incrementing by one. See figure 10.4, page 95, for an example of stvid marking an unidentified trail red. In this case, the trail was created by an airplane, but stvid would do the same with an unidentified satellite trail.

### 10.3.7 .dat Data Files

For each trail detected as shown in previous sections, such as for which a PNG file was created, stvid will output a .dat file. The .dat filenames corresponding to the figures at 10.2, 10.3, and 10.4 are:

```
2022-08-23T04:16:26.633_48473_catalog.dat
2022-08-23T04:16:26.633_52718_catalog.dat
2022-08-23T04:16:26.633_90000_unid.dat
```

**Figure 10.3:** stvid PNG of the satellite trail of NORAD ID 52718 identified in red.

Note, there is no .dat file created corresponding to the 2022-08-23T04:16:26.633.fits.png file, since it doesn't show detected trails.

The .dat file contents look like this, for NORAD ID 48473:

```
48473 21 040AX 9999 G 20220823041631625 17 25 1533406+483563 37 S
```

XXX This is the IOD ? XXX The first field is the NORAD ID. The fourth field looks like COSPAR. XXX Large number starting with 2022 is date and time stamp.

The .dat file contents look like this, for NORAD ID 52718:

```
52718 22 056C 9999 G 20220823041631625 17 25 1527277+381243 37 S
```

The .dat file contents look like this, for the unidentified trail (the airplane):

```
90000 22 500A 9999 G 20220823041631625 17 25 1457613+535844 37 S
```

### 10.3.8 stvid .csv Files

During processing, stvid generates (at least!) three CSV files. For the observation discussed above, starting with figure 10.1, the following CSV files are generated:

### 10.3. DATA FILES

Figure 10.4: stvid PNG of an unidentified trail in red.

```
2022-08-23T04:16:26.633_hough.csv
2022-08-23T04:16:26.633_predict.csv
2022-08-23T04:16:26.633_threshold.csv
```

#### stvid hough.csv Files

Full contents of the 2022-08-23T04:16:26.633\_hough.csv file:

# Acronyms

---

**Alt/Az mount** a simple two-axis mount for supporting and rotating an instrument about two perpendicular axes — one vertical and the other horizontal. Rotation about the vertical axis varies the azimuth (compass bearing) of the pointing direction of the instrument. Rotation about the horizontal axis varies the altitude angle (angle of elevation) of the pointing direction. These mounts are used, for example, with telescopes, cameras, and radio antennas.<sup>1</sup> (Altazimuth mount)

**BDS** BeiDou Navigation Satellite System. (BeiDou Navigation Satellite System)

**BIOS** Basic Input/Output System. (Basic Input/Output System)

**BSD** Berkeley Software Distribution. (Berkeley Software Distribution)

**CCD** charge-coupled device. (charge-coupled device)

**CMOS** Complementary metal-oxide-semiconductor (pronounced “see-moss”). (Complementary metal-oxide-semiconductor)

**COTS** Commodity off the shelf. (Commodity off the shelf)

**CPU** central processing unit. (central processing unit)

**CSV** Comma Separated Value. (Comma Separated Value)

**DB** Database. (Database)

**DC** Direct current. (Direct current)

**DCS** distributed control system. (distributed control system)

**DFSG** Debian Free Software Guidelines is a set of guidelines that the Debian Project uses to determine whether a software license is a Free Software license, which in turn is used to determine whether a piece of software can be included in Debian. The DFSG is part of the Debian Social Contract.<sup>2</sup> (Debian Free Software Guidelines)

**DSLR** digital single-lens reflex. (digital single-lens reflex)

**EQ** Equatorial. (equatorial)

**FITS** Flexible Image Transport System is an open standard defining a digital file format useful for storage, transmission and processing of data: formatted as multi-dimensional arrays (for example a 2D image), or tables. FITS is the most commonly used digital file format in astronomy. The FITS standard was designed specifically for astronomical data, and includes provisions such as describing photometric and spatial calibration information, together with image origin metadata.<sup>3</sup> (Flexible Image Transport System)

**FLIR** Forward-looking infrared. (Forward-looking infrared)

**FLOSS** Free/libre and open-source software. See also: FOSS. (Free/libre and open-source software)

**FOSH** Free open-source hardware. See also: OSH. (Free open-source hardware)

**FOSS** free and Open Source software is a term used to refer to groups of software consisting of both Free Software and OSS where anyone is freely licensed to use, copy, study, and change the software in any way, and the source code is openly shared so that people are encouraged to voluntarily improve the design of the software. This is in contrast to proprietary software, where the software is under restrictive copyright licensing and the source code is usually hidden from the users. FOSS maintains the software user's civil liberty rights. Other benefits of using FOSS can include decreased software costs, increased security and stability (especially in regard to malware), protecting privacy, education, and giving users more control over their own hardware. Free and open-source operating systems such as Linux and descendants of BSD are widely utilized today, powering millions of servers, desktops, smartphones (e.g., Android), and other devices. Free-software licenses and Open Source licenses are used by many software packages. The free software movement and the Open Source software movement are online social movements behind widespread production and adoption of FOSS, with the former preferring to use the terms FLOSS or free/libre.<sup>4</sup> (free and open-source software)

**FOV** Field of view. (Field of View)

**GHz** gigahertz. (gigahertz)

**GLONASS** Global Navigation Satellite System. (Global Navigation Satellite System)

**GNSS** Global Navigation Satellite System. (Global Navigation Satellite System)

**GNU** "GNU's Not Unix!" is an extensive collection of Free Software, which can be used as an OS or can be used in parts with other OSs. The use of the completed GNU tools led to the family of operating systems popularly known as Linux. Most of GNU is licensed under the

<sup>9</sup><https://libre.space/about-us/>

**NASA** is an independent agency of the US federal government responsible for the civil space program, aeronautics research, and space research.<sup>10</sup> (National Aeronautics and Space Administration)

**NGC** New General Catalogue of Nebulae and Clusters of Stars. (New General Catalogue of Nebulae and Clusters of Stars)

**NORAD** North American Aerospace Defense Command is a combined organization of the United States and Canada that provides aerospace warning, air sovereignty, and protection for Canada and the continental United States.<sup>11</sup> (North American Aerospace Defense Command)

**NORAD ID** is a sequential nine-digit number assigned by the USSPACECOM in the order of launch or discovery to all artificial objects in the orbits of Earth and those that left Earth's orbits. Space Command shares the catalog via `space-track.org`, which is maintained by the 18th SDS. NORAD ID is also known as a satellite catalog number.<sup>12</sup> (North American Aerospace Defense Catalog Number)

**NTP** Network Time Protocol. (Network Time Protocol)

**NUC** Next Unit of Computing. (Next Unit of Computing)

**OS** An operating system is system software that manages computer hardware, software resources, and provides common services for computer programs.<sup>13</sup> (Operating System)

**OSAT** open-source appropriate technology. (open-source appropriate technology)

**OSH** open-source hardware consists of physical artifacts of technology designed and offered by the open-design movement. Both FOSS and open-source hardware are created by the open-source culture movement and apply a like concept to a variety of components. It is sometimes, thus, referred to as FOSH. The term usually means that information about the hardware is easily discerned so that others can make it—coupling it closely to the maker movement. Hardware design (i.e. mechanical drawings, schematics, bills of material, PCB layout data, HDL source code and integrated circuit layout data), in addition to the software that drives the hardware, are all released under free/libre terms. The original sharer gains feedback and potentially improvements on the design from the FOSH community. There is now significant evidence that such sharing can drive a high return on investment for the scientific community. It is not enough to merely use an Open Source license; an Open Source product or project will follow Open Source principles, such as modular design and community collaboration.<sup>14</sup> (open-source hardware)

**OSS** open-source software is computer software that is released under a license in which the copyright holder grants users the rights to use, study, change, and distribute the software and its source code to anyone and for any purpose. Open-source software may be developed in a collaborative public manner. Open-source software is a prominent example of open collaboration, meaning any capable user is able to participate online in development, making the number of possible contributors indefinite. The ability to examine the code facilitates public trust in the software. Open source code can be used for studying and allows capable end users to adapt software to their personal needs in a similar way user scripts and custom style sheets allow for web sites, and eventually publish the modification as a fork for users with similar preference.<sup>15</sup> (open-source software)

**PaaS** Platform as a Service. (Platform as a Service)

**PC** Personal Computer. (Personal Computer)

**PCB** Printed circuit board. (Printed Circuit Board)

**PIP** Package Installer for Python. (Package Installer for Python)

**PNG** Portable Network Graphics. (Portable Network Graphics)

**SDR** Software-defined radio is a radio communication system where components that have been traditionally implemented in analog hardware (e.g. mixers, filters, amplifiers, modulators/demodulators, detectors, etc.) are instead implemented by means of software on a PC or embedded system. SDRs are used in SatNOGS ground stations.<sup>18</sup> (Software-defined radio)

**SDS** Space Defense Squadron. (Space Defense Squadron)

**SGP** Simplified General Perturbations models apply to near earth objects with an orbital period of less than 225 minutes. Simplified perturbations models are a set of five mathematical models (SGP, SGP4, SDP4, SGP8 and SDP8) used to calculate orbital state vectors of satellites and space debris relative to the Earth-centered inertial coordinate system. This set of models is often referred to collectively as SGP4 due to the frequency of use of that model particularly with TLE sets produced by NORAD and NASA. These models predict the effect of perturbations caused by the Earth’s shape, drag, radiation, and gravitation effects from other bodies such as the sun and moon. See also: SDP.<sup>19</sup> (Simplified General Perturbations)

**SIDLOC** Spacecraft Identification and Localization. (Spacecraft Identification and Localization)

**SIP** Simple Imaging Polynomial. (Simple Imaging Polynomial)

**SSA** Space Situational Awareness. (Space Situational Awareness)

**TLE** two-line element set is a data format encoding a list of orbital elements of an Earth-orbiting object for a given point in time, the epoch. Using a suitable prediction formula, the state (position and velocity) at any point in the past or future can be estimated to some accuracy. TLEs can describe the trajectories only of Earth-orbiting objects. TLEs are widely used as input for projecting the future orbital tracks of space debris for purposes of characterizing “future debris events to support risk analysis, close approach analysis, collision avoidance maneuvering” and forensic analysis. The format was originally intended for punched cards, encoding a set of elements on two standard 80-column cards.<sup>20</sup> (two-line element set)

**UHF** Ultra High Frequency is the ITU designation for radio frequencies in the range between 300 MHz and 3 GHz, also known as the decimetre band as the wavelengths range from one meter to one tenth of a meter (one decimeter). Lower frequency signals fall into the VHF or lower bands.<sup>21</sup> (Ultra High Frequency)

**USB** Universal Serial Bus. (Universal Serial Bus)

**USM** is a type of piezoelectric motor powered by the ultrasonic vibration of a component, the stator, placed against another component, the rotor or slider depending on the scheme of operation (rotation or linear translation). One common application of ultrasonic motors

## Glossary

---

**Amateur radio** is the use of the radio frequency spectrum for purposes of non-commercial exchange of messages, wireless experimentation, self-training, private recreation, radiosport, contesting, and emergency communications.<sup>24</sup>

**Antenna** the interface between radio waves propagating through space and electric currents moving in metal conductors, used with a transmitter or receiver.<sup>25</sup>

**Appropriate technology** is a movement (and its manifestations) encompassing technological choice and application that is small-scale, affordable by locals, decentralized, labor-intensive, energy-efficient, environmentally sustainable, and locally autonomous. Appropriate technology has been used to address issues in a wide range of fields. Today appropriate technology is often developed using Open Source principles, which have led to OSAT and thus many of the plans of the technology can be freely found on the Internet.<sup>26</sup>

**Astrograph** is a telescope designed for the sole purpose of astrophotography. Astrographs are mostly used in wide-field astronomical surveys of the sky and for detection of objects such as asteroids, meteors, and comets.<sup>27</sup>

**AstroImageJ** Application for astronomy and satellite image analysis.<sup>28</sup>

**Astronomical catalogue** is a list or tabulation of astronomical objects, typically grouped together because they share a common type, morphology, origin, means of detection, or method of discovery. The oldest and largest are star catalogues. Hundreds have been published, including general ones and special ones for such items as infrared stars, variable stars, giant stars, multiple star systems, and star clusters. Since the late 20th century catalogs are increasingly often compiled by computers from an automated survey, and published as computer files rather than on paper.<sup>29</sup>

**Binning** is the process of combining adjacent pixels throughout an image, by summing or averaging their values, during or after readout. Charge from adjacent pixels in CCD image

sensors and some other image sensors can be combined during readout, increasing the line rate or frame rate. In the context of image processing, binning is the procedure of combining clusters of adjacent pixels, throughout an image, into single pixels. For example, in 2x2 binning, an array of 4 pixels becomes a single larger pixel, reducing the number of pixels to 1/4 and halving the image resolution in each dimension. The result can be the sum, average, median, minimum, or maximum value of the cluster. This aggregation, although associated with loss of information, reduces the amount of data to be processed, facilitating analysis. The binned image has lower resolution, but the relative noise level in each pixel is generally reduced. Also called pixel binning.<sup>30</sup>

**C** is a general-purpose computer programming language. It was created in the 1970s by Dennis Ritchie, and remains very widely used and influential. By design, C's features cleanly reflect the capabilities of the targeted CPUs. It has found lasting use in OSs, device drivers, protocol stacks, though decreasingly for application software. C is commonly used on computer architectures that range from the largest supercomputers to the smallest microcontrollers and embedded systems. C is used in the sattools suite of applications.<sup>31</sup>

**Celestron** is an American company based in Torrance, California, United States, that manufactures telescopes and distributes telescopes, binoculars, spotting scopes, microscopes, and accessories.<sup>32</sup>

**CubeSat** is a class of miniaturized satellite based around a form factor consisting of 10 cm (3.9 in) cubes. CubeSats have a mass of no more than 2 kg per unit, and often use COTS components for their electronics and structure. CubeSats are put into orbit by deployers on the ISS, or launched as secondary payloads on a launch vehicle. More than a thousand CubeSats have been launched.<sup>33</sup>

**Daemon** a service in a Unix OS.<sup>34</sup>

**Debian** a GNU/Linux distribution composed of free and open-source software, developed by the community-supported Debian Project, which was established by Ian Murdock on August 16, 1993. Debian is the basis for many other distributions, notably Ubuntu. Debian is one of the oldest operating systems based on the Linux kernel.<sup>35</sup>

**Docker** is a set of PaaS products that use OS-level virtualization to deliver software in packages called containers.<sup>36</sup>

**Embedded system** is a computer system—a combination of a computer processor, computer memory, and input/output peripheral devices—that has a dedicated function within a larger mechanical or electronic system. It is embedded as part of a complete device often including electrical or electronic hardware and mechanical parts. Because an

embedded system typically controls physical operations of the machine that it is embedded within, it often has real-time computing constraints. embedded systems control many devices in common use today. it was estimated that ninety-eight percent of all microprocessors manufactured were used in embedded systems.<sup>37</sup>

**Firmware** firmware is a specific class of computer software that provides the low-level control for a device's specific hardware. Firmware, such as the BIOS of a PC, may contain basic functions of a device, and may provide hardware abstraction services to higher-level software such as OSs. For less complex devices, firmware may act as the device's complete OS, performing all control, monitoring and data manipulation functions. Typical examples of devices containing firmware are embedded systems (running embedded software), home and personal-use appliances, computers, and computer peripherals.<sup>38</sup>

**Free Software** or libre software, is computer software distributed under terms that allow users to run the software for any purpose as well as to study, change, and distribute it and any adapted versions. Free software is a matter of liberty, not price; all users are legally free to do what they want with their copies of a free software (including profiting from them) regardless of how much is paid to obtain the program. Computer programs are deemed "free" if they give end-users (not just the developer) ultimate control over the software and, subsequently, over their devices.<sup>39</sup>

**GoTo** In amateur astronomy, "GoTo" refers to a type of telescope mount and related software that can automatically point a telescope at astronomical objects that the user selects. Both axes of a GoTo mount are driven by a motor and controlled by a computer. It may be either a microprocessor-based integrated controller or an external PC. This differs from the single-axis semi-automated tracking of a traditional clock-drive equatorial mount. The user can command the mount to point the telescope to the celestial coordinates that the user inputs, or to objects in a pre-programmed database including ones from the Messier catalogue, the NGC, and even major Solar System bodies (the Sun, Moon, and planets). Like a standard EQ mount, EQ GoTo mounts can track the night sky by driving the right ascension axis. Since both axes are computer controlled, GoTo technology also allows telescope manufacturers to add EQ tracking to mechanically simpler altazimuth mounts.<sup>40</sup>

**GPhoto** is a set of software applications and libraries for use in digital photography. gPhoto supports not just retrieving of images from camera devices, but also upload and remote controlled configuration and capture, depending on whether the camera supports those features. gPhoto supports more than 2500 cameras.<sup>41</sup>

**Gpsd** is a computer software program that collects data from a GPS receiver and provides the data via a network to potentially multiple client applications in a server-client application architecture. Gpsd may be run as a daemon to operate transparently as a background

task of the server. The network interface provides a standardized data format for multiple concurrent client applications.<sup>42</sup>

**Grafana** is a multi-platform Open Source analytics and interactive visualization web application. It provides charts, graphs, and alerts for the web when connected to supported data sources. Users can create complex monitoring dashboards using interactive query builders. It is used by the SatNOGS project to visualize satellite telemetry.<sup>43</sup>

**Ground station** a setup of equipment such as computers, cameras, SDRs, antennas, and receivers, located on Earth, observing space.

**Hough3d-code** is a software application for Iterative Hough Transform for Line Detection in 3D Point Clouds.<sup>44</sup>

**KStars** is a planetarium program. It provides an accurate graphical representation of the night sky, from any location on Earth, at any date and time. The display includes up to 100 million stars (with additional addons), 13,000 deep sky objects, constellations from different cultures, all 8 planets, the Sun and Moon, and thousands of comets, asteroids, satellites, and supernovae. It has features to appeal to users of all levels, from informative hypertext articles about astronomy, to robust control of telescopes and CCD cameras, and logging of observations of specific objects.<sup>45</sup>

**Lagrange point** are points of equilibrium for small-mass objects under the influence of two massive orbiting bodies. At the Lagrange points, the gravitational forces of the two large bodies and the centrifugal force balance each other. This can make Lagrange points an excellent location for satellites, as few orbit corrections are needed to maintain the desired orbit. Small objects placed in orbit at Lagrange points are in equilibrium in at least two directions relative to the center of mass of the large bodies.<sup>46</sup>

**Libre** The English adjective free is commonly used in one of two meanings: “at no monetary cost” (gratis) and “with little or no restriction” (libre). This ambiguity of free can cause issues where the distinction is important, as it often is in dealing with laws concerning the use of information, such as copyright and patents. The terms gratis and libre may be used to categorise computer programs, according to the licenses and legal restrictions that cover them, in the Free Software and Open Source communities, as well as the broader free culture movement. For example, they are used to distinguish freeware (software gratis) from Free Software (software libre). “Think free as in free speech, not free beer.” – Richard Stallman.<sup>47</sup>

**Linux** is a free and open-source, monolithic, modular, multitasking, Unix-like operating system kernel. It was originally authored in 1991 by Linus Torvalds for his i386-based PC, and it was soon adopted as the kernel for the GNU OS, which was written to be a free (libre) replacement for Unix.<sup>48</sup>

**Mast** typically tall structures designed to support antennas for telecommunications and broadcasting.<sup>49</sup>

**Matrix** an open standard and communication protocol for real-time communication.<sup>50</sup>

**Open Source** is source code that is made freely available for possible modification and redistribution. Products include permission to use the source code, design documents, or content of the product. The open-source model is a decentralized software development model that encourages open collaboration. A main principle of open-source software development is peer production, with products such as source code, blueprints, and documentation freely available to the public. The open-source movement in software began as a response to the limitations of proprietary code. The model is used for projects such as in open-source appropriate technology.<sup>51</sup>

**OpenCV** Open Source Computer Vision Library is a library of programming functions mainly aimed at real-time computer vision.<sup>52</sup>

**Optical ground station** a ground station using optical equipment (cameras) instead of antennas.

**Orbit** is the curved trajectory of an object such as the trajectory of a planet around a star, or of a natural satellite around a planet, or of an artificial satellite around an object or position in space such as a planet, moon, asteroid, or Lagrange point. Normally, orbit refers to a regularly repeating trajectory, although it may also refer to a non-repeating trajectory. To a close approximation, planets and satellites follow elliptic orbits, with the center of mass being orbited at a focal point of the ellipse, as described by Kepler's laws of planetary motion. For most situations, orbital motion is adequately approximated by Newtonian mechanics, which explains gravity as a force obeying an inverse-square law. However, Albert Einstein's general theory of relativity, which accounts for gravity as due to curvature of spacetime, with orbits following geodesics, provides a more accurate calculation and understanding of the exact mechanics of orbital motion.<sup>53</sup>

**Perturbation** is the complex motion of a massive body subjected to forces other than the gravitational attraction of a single other massive body. The other forces can include a third (fourth, fifth, etc.) body, resistance, as from an atmosphere, and the off-center attraction of an oblate or otherwise misshapen body.<sup>54</sup>

**Photon** is an elementary particle that is a quantum of the electromagnetic field, including electromagnetic radiation such as light and radio waves, and the force carrier for the electromagnetic force. Photons are massless, so they always move at the speed of light in vacuum, 299,792,458 meters/second.<sup>55</sup>

**Pipeline** is a set of data processing elements connected in series, where the output of one element is the input of the next one. The elements of a pipeline are often executed in parallel or in time-sliced fashion.<sup>56</sup>

**Plate solver** is software implementing a technique used in astronomy and applied on celestial images. Solving an image is finding match between the imaged stars and a star catalogue. The solution is a math model describing the corresponding astronomical position of each image pixel. The position of reference catalogue stars has to be known to a high accuracy so an astrometric reference catalogue is used. The image solution contains a reference point, often the image centre, image scale, image orientation and in some cases an image distortion model. With the astrometric solution it is possible to: 1) Calculate the celestial coordinates of any object on the image. 2) Synchronize the telescope mount or satellite pointing position to the center of the image taken. Astrometric solving programs extract the star x,y positions from the celestial image, groups them in three-star triangles or four-star quads. Then it calculates for each group a geometric hash code based on the distance and/or angles between the stars in the group. It then compares the resulting hash codes with the hash codes created from catalogue stars to find a match. If it finds sufficient statistically reliable matches, it can calculate transformation factors. There are several conventions to model the transformation from image pixel location to the corresponding celestial coordinates. The simplest linear model is called the WCS. A more advanced convention is SIP describing the transformation in polynomials to cope with non-linear geometric distortion in the celestial image, mainly caused by the optics.<sup>57</sup>

**Python** is a high-level, interpreted, general-purpose programming language. Its design philosophy emphasizes code readability. It is often described as a “batteries included” language due to its comprehensive standard library. Python consistently ranks as one of the most popular programming languages. It is one of the main languages of the SatNOGS project and stvid.<sup>58</sup>

**Raspberry Pi** is a series of small SBCs. It is typically used by computer and electronic hobbyists as an embedded system.<sup>59</sup>

**Rotator** a device used to change the orientation, within the horizontal plane, of a directional antenna. Most antenna rotators have two parts, the rotator unit and the controller. The controller is normally placed near the equipment which the antenna is connected to, while the rotator is mounted on the antenna mast directly below the antenna. Rotators are commonly used in amateur radio.<sup>60</sup>

**Satellite** is an object intentionally placed into orbit in outer space. Except for passive satellites, most satellites have an electricity generation system for equipment on board. Most satellites also have a method of communication to ground stations, called transponders.

Many satellites use a standardized bus to save cost and work, the most popular of which is small CubeSats. Similar satellites can work together as a group, forming constellations.<sup>61</sup>

**Satid** is part of sattools.<sup>62</sup>

**SatNOGS** Open Source global network of satellite ground stations.<sup>63</sup>

**SatNOGS Optical** is a project by the LSF to add optical ground stations to the SatNOGS network.<sup>64</sup>

**Satpredict** is a software application to compute satellite predictions. It is used by stvid.<sup>65</sup>

**Sattools** Satellite Tracking Toolkit. The main `sattools` applications are being ported to stvid and other related Python applications.<sup>66</sup>

**Sky chart** or star chart or star map, also called or sky map, is a map of the night sky. Astronomers divide these into grids to use them more easily. They are used to identify and locate constellations and astronomical objects such as stars, nebulae, and galaxies. They have been used for human navigation since time immemorial. Note that a sky chart differs from an astronomical catalogue, which is a listing or tabulation of astronomical objects for a particular purpose.<sup>67</sup>

**Skymap** is part of sattools. Visualize satellites on a map of the sky.<sup>68</sup>

**Slew** The process of rotating a telescope to observe a different region of the sky.<sup>69</sup>

**Software repository** or repo for short, is a storage location for software packages. Often a table of contents is also stored, along with metadata. A software repository is typically managed by source control or repository managers. Package managers allow automatically installing and updating repositories (sometimes called “packages”).<sup>70</sup>

**Star catalogue** is an astronomical catalogue that lists stars. In astronomy, many stars are referred to simply by catalogue numbers. There are a great many different star catalogue which have been produced for different purposes over the years. Most modern catalogues are available in electronic format and can be freely downloaded from space agencies’ data centres. The largest is being compiled from the spacecraft Gaia and thus far has over a billion stars. Completeness and accuracy are described by the faintest limiting magnitude and the accuracy of the positions.<sup>71</sup>

**Star trail** is a type of photograph that uses long exposure times to capture diurnal circles, the apparent motion of stars in the night sky due to Earth’s rotation. A star-trail photograph

shows individual stars as streaks across the image, with longer exposures yielding longer arcs.<sup>72</sup>

**Stvid** Satellite tools video application for acquiring and processing sky images.<sup>73</sup>

**Teledyne FLIR** a subsidiary of Teledyne Technologies, specializes in the design and production of thermal imaging cameras and sensors. The name is based on the acronym FLIR.<sup>74</sup>

**Telemetry** is the in situ collection of measurements or other data at remote points and their automatic transmission to receiving equipment (telecommunication) for monitoring. The word is derived from the Greek roots tele, “remote”, and metron, “measure”. Although the term commonly refers to wireless data transfer mechanisms (e.g., using radio, ultrasonic, or infrared systems), it also encompasses data transferred over other media such as a telephone or computer network, optical link or other wired communications like power line carriers.<sup>75</sup>

**Telescope** is an optical instrument using lenses, curved mirrors, or a combination of both to observe distant objects, or various devices used to observe distant objects by their emission, absorption, or reflection of electromagnetic radiation. The word telescope now refers to a wide range of instruments capable of detecting different regions of the electromagnetic spectrum, and in some cases other types of detectors.<sup>76</sup>

**Toolchain** is a set of programming tools that is used to perform a complex software development task or to create a software product, which is typically another computer program or a set of related programs.<sup>77</sup>

**Unix** is a family of multitasking, multiuser computer OSs that derive from the original AT&T Unix, whose development started in 1969 at the Bell Labs research center by Ken Thompson, Dennis Ritchie, and others.<sup>78</sup>

**Upstream** refers to a direction toward the original authors or maintainers of software that is distributed as source code, and is a qualification of either a version (released by the original authors, based on their upstream source code), a bug or a patch.<sup>79</sup>
